

Companion

The personal AI that belongs to you.

Advait Paliwal

companion.ai

This has to be built full time now.

Personal AI needs two years of uninterrupted building with real people and machines.

The loop is shipping, observing, correcting, and redeploying in real lives.

The Fellowship gives that loop two uninterrupted years.

AI started as distribution. Platform AI became rental.

Original promise: AI as an extension of individual will, broadly distributed, with open research and shared benefits.

Current path: the strongest models are closed, rented, rationed, and revocable by the platforms that run them.

Companion is the fork: intimate AI should be owned by the person it learns.

A personal AI has to be owned by the person.

The valuable data is the person's files, routines, corrections, relationships, and places.

The model has to remember across years and across product boundaries.

The person needs the right to keep it, move it, improve it, and run it when a platform changes policy.

Cloud AI is a utility. Personal AI is property.

Companion is the software loop that makes AI personal.

Today: Companion runs across phone, web, and the user's computer.

It learns from tasks, corrections, repeated workflows, files, and local context.

The next form is a local AI computer that keeps the person's memory and model under their control.

The first buyers already describe the same machine.

Biotech lab: bought smart speakers and built a rough Signal / SMS / iPad / phone agent for a bounded technical world.

Small business owner: asked for cameras, speakers, microphones, and local compute so agents could watch the shop and keep running.

Different places. Same demand: an AI that lives with a world and keeps learning it.

The AI computer is the physical form of ownership.

Phone, web, local apps, files, rooms, and voice feed one owned machine.

Hard reasoning can burst to cloud while memory stays local.

The product is the owned personal AI system, not another chatbot subscription.

The hardware wave is real. Companion makes it personal.

270M+ PCs shipped worldwide in 2025.

143M AI PCs forecast for 2026.

USD 207B in GPU and AI accelerator spend expected in 2025.

NVIDIA DGX Spark shows a local inference class up to 200B parameters.

Compute is arriving. The opening is making local compute into a personal product.

Always-on personal agents make renting intelligence break.

Renting cloud compute for one 24/7 personal agent: roughly USD 1.4K to USD 2.2K per month.

Owning the local machine after purchase: roughly USD 27 per month in electricity.

For one person running all day, cloud margin becomes rent.

The moat is compounding context.

A person's private history compounds with each use.

Every correction, habit, workflow, file, and place makes the AI harder to replace.

A smarter generic model can still be worse for the person who trained Companion.

Ownership makes the most valuable data usable without giving it to a platform.

This becomes a company through a product line.

Brain: USD 2.5K to USD 5K for the local AI computer class.

Peripherals: USD 99 to USD 499 for microphones, speakers, cameras, and sensors.

Support: USD 20 to USD 50 per month for updates, backup, and cloud overflow.

The point is one consumer system people can buy, own, and keep improving.

Two Thiel years produce the first owned personal AI machines.

USD 250K, no equity, two years, and the Fellowship network are exactly the missing inputs.

Deploy 5 to 10 design partners across lab, small business, and prosumer workflows.

Ship the local AI computer prototype.

Prove memory compounding in repeated tasks.

Turn the prototype into a product people can buy, own, and live with.
